If you are the author of this thesis and wish to have the whole thesis loaded here, please contact the University of Canberra Library at e-theses@canberra.edu.au Your thesis will then be available on the www providing greater access.
A COMPARISON OF FIELD AND LABORATORY TESTING OF SPORTS SPECIFIC FITNESS FOR FEMALE FIELD HOCKEY PLAYERS

Nining Widyah Kusnanik

A thesis submitted in partial fulfilment of the requirements for the degree of Master of Applied Science at the University of Canberra

December 2001
I would like to thank the following people for their support whilst undertaking this thesis:

- Associate Professor Alan Roberts who was my project supervisor. He provided me continuous support, encouragement, sound advice and checked my drafts and ideas for long hours. He also provided me with much valued advice, feedback, criticism, and organisation of the field and laboratory equipment and instructions and helped me in gathering the subjects.

- Each study subject who formed the basis of this research.

- Kelly Linaker and Ben Rattray who helped me with great assistance during the testing in Australia.

- Prof. Dr. Primadi Tabrani, the Indonesian Hockey President, who gave me permission to collect data on the Indonesian female field hockey players and provided me some information about hockey in Indonesia.

- Drs. Djamilus and Hafiludin, S.Pd who helped me during the testing in Indonesia.

- Peter Fogarty and Tom Kaveney who allowed their athletes to participate in this study.

- Don Jones who provided some information about hockey and helped me by reading my drafts.

- My family who provided continued support throughout my academic career especially, my parents who looking after my daughter Cindy Olga Rizky.
ABSTRACT

There are many methods to measure the physical fitness of athletes, including tests that can be applied in the field or in the laboratory. Much of the recent research with regard to fitness of team sport players has been undertaken using laboratory testing to measure aerobic power, anaerobic power and capacity, strength and flexibility. Field tests are an alternative method to measure the fitness of players without the expense, time and expertise required for the laboratory testing, especially in developing countries.

The purpose of this study is to establish procedures for the application of contemporary sports science practice for Indonesian female field hockey players, including determination of the precision of field tests of the physical and performance characteristics of field hockey players in Indonesia; determination of the physical and performance characteristics of Indonesian female field hockey players; identification of the performance demands and distance covered during competitive field hockey at the national level in Indonesia; comparison of the physical and performance characteristics of national level female field hockey players in Indonesia with those of club level players in Australia; and determination of the relationships between field and laboratory tests of physiological performance capacity for field hockey.

This study was conducted on 26 Indonesian and 11 Australian female field hockey players. The mean values for age, height, mass, BMI and skinfold thickness of the Indonesian players were 22.0±3.4 years, 156.3±4.9cm, 51.2±6.2kg, 20.9±2.0kg-m⁻², and 99.4±17.9mm, respectively. The mean values for VO₂max (20m srt), VJ, leg power, SBJ, sit and reach, and 40m sprint were 38.7±3.2ml-kg⁻¹-min⁻¹, 39.3±4.3cm, 70.7±1.0kg-m-sec⁻¹, 183.3±17.0cm, +14.7±5.7cm, 6.99±10.39s, respectively. The mean HR values at the end of the first and second half of a game of field hockey were 171.0±8.7bpm and 161.3±18.2bpm, respectively. The mean values for blood lactate concentration at the end of the first and second half of play were 5.3±1.2mmol-L⁻¹ and 5.1±1.7mmol-L⁻¹, respectively. The mean total distance covered by the players during the complete game was 2841.8±432.2m. The mean time spent walking and at more than walking pace (jogging, running and sprinting) during the game were 46:08min and 24:18min, respectively. The mean values for temperature and humidity were 38.2±4.1°C and 57.5±9.8%, respectively.

The mean values for age, height, mass, BMI and skinfold thickness of the Australian players were 24.0±3.9 years, 165.7±3.4cm, 64.8±4.1kg, 24.0±1.6kg-m⁻², and 77.9±17.3mm, respectively. The mean values for VO₂max (20m srt), VJ, leg power, SBJ, sit and reach, and 40m sprint were 42.1±4.7ml-kg⁻¹-min⁻¹, 37.5±4.4cm, 87.2±7.0kg-m-sec⁻¹, 174.9±18.3cm, +11.2±6.4cm, and 6.46±0.30s, respectively. The mean values for VO₂max (treadmill running), isokinetic strength, 10 sec maximal ergometer sprint test, and 5 x 6 sec repeat effort cycle ergometer test were 46.3±3.8ml-kg⁻¹-min⁻¹, 88.2±10.6N-m (left hamstring), 58.1±13.8N-m (right hamstring), 152.9±27.0N-m (left quadriceps), 152.6±19.2N-m (right quadriceps), 58.6±6.9% (left hamstring/quadriceps ratio), 57.9±5.3% (right hamstring/quadriceps ratio), 103.7±10.83kg⁻¹ (total work), 12.5±1.0W-kg⁻¹ (peak power), 261.2±25.63kg⁻¹ (total work), 9.3±5.4% (work decrement) and 5.7±3.8% (power decrement).
respectively. The mean values for temperature and humidity were 11.8±1.8°C (outdoor), 20.5±3.3°C (indoor), 60.4±2.6% (outdoor) and 50.6±6.8% (indoor), respectively.

There were no significant differences between Indonesian and Australian players in age, VO$_2$max (20m SRT), VJ, SBJ, S&R, and acceleration measurements (p>0.05). However, there were significant differences between Indonesian and Australian players in height, mass, BMI, skinfold thickness, leg power, speed, and combined acceleration and speed measurements (p<0.05). The Australian players were significantly taller and heavier than the Indonesian players. The Indonesian players had higher values for the sum of 7 skinfolds than the Australian players. The Australian players had significantly higher values for leg power than the Indonesian players. The Australian players were significantly faster than the Indonesian players.

Among the Australian players there was a significant difference between the VO$_2$max value during treadmill running and the VO$_2$max estimated from the 20m SRT (t=0.003, p<0.05). There was a significant correlation between the VO$_2$max value during treadmill running and the VO$_2$max estimated from the 20m SRT (r=0.66, p<0.05). The correlations between the leg power (estimated from the vertical jump test) and the isokinetic power of the quadriceps muscle group was not significant (p>0.05). The correlation between the running speed (estimated from the combined acceleration and speed score from the 40m sprint test) and the peak power from the 10s maximal ergometer sprint test (r=-0.55) was not significant (p>0.05).

In conclusion, the present study found that the Indonesian female field hockey players (at the national level) were comparable to the Australian female field hockey players (at the club level) in some physical and performance test results. However, they were also different on other physical and performance characteristic measurements, with the Indonesian players generally have lower values, for other performance measurements.
